

# Climate Change, Adaptation, and Sovereign Risk

Sarah Duffy

University of Oxford

January 2026

## Motivation: Adaptation and Sovereign Risk

Climate change is projected to increase the frequency and severity of natural disasters

- Climate Policy attention turning towards **adaptation**: adjusting to this 'new normal'
- Adaptation can limit damages, but it is costly

## Motivation: Adaptation and Sovereign Risk

Climate change is projected to increase the frequency and severity of natural disasters

- Climate Policy attention turning towards **adaptation**: adjusting to this 'new normal'
- Adaptation can limit damages, but it is costly

Many disaster-prone economies also **fiscally constrained**

- Climate change likely to increase borrowing costs further: climate defaults?
- Calls for '**debt relief for climate resilience**'

# Motivation: Adaptation and Sovereign Risk

Climate change is projected to increase the frequency and severity of natural disasters

- Climate Policy attention turning towards **adaptation**: adjusting to this 'new normal'
- Adaptation can limit damages, but it is costly

Many disaster-prone economies also **fiscally constrained**

- Climate change likely to increase borrowing costs further: climate defaults?
- Calls for '**debt relief for climate resilience**'

This paper:

1. How does sovereign risk affect adaptation (and vice versa)?
2. Could debt relief help?

# Cyclone Adaptation

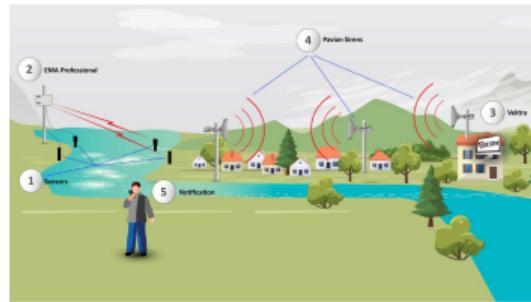

# Cyclone Adaptation

Green Infrastructure: Mangroves

Early Warning Systems

## Takeaways

- **Analytical Model:** Sovereign default + natural disasters, endogenous adaptation
  - Default risk constrains adaptation of emerging markets: Adaptation Trap

## Takeaways

- **Analytical Model:** Sovereign default + natural disasters, endogenous adaptation
  - Default risk constrains adaptation of emerging markets: Adaptation Trap
- **Data:** Novel adaptation measure from government budgets
  - Adaptation increasing in exposure + ratings (1 SD → \$250m)
  - Hurricane causes default prob ↑, driven by low adaptation economies

## Takeaways

- **Analytical Model:** Sovereign default + natural disasters, endogenous adaptation
  - Default risk constrains adaptation of emerging markets: Adaptation Trap
- **Data:** Novel adaptation measure from government budgets
  - Adaptation increasing in exposure + ratings (1 SD → \$250m)
  - Hurricane causes default prob ↑, driven by low adaptation economies
- **Quantitative Model:** long term debt, adaptation capital
  - Counterfactual: no default option
  - Adaptation investment / GDP in Caribbean is 13% lower
  - GDP effects of hurricanes are 10% higher - increases with climate change
  - Debt relief can help: interest free loan, adaptation linked bond

## Relation to the Literature

- Climate Change and Sovereign Risk
  - Climate Change exacerbates fiscal vulnerabilities (Mallucci, 2022; Phan + Schwartzmann, 2023)
  - **Contribution:** Endogenous Adaptation
- Climate Change and Adaptation
  - Hong et al, 2023; Fried, 2021; Lane, 2024
  - Latent approach: (e.g. Burke et al, 2024). Direct: (e.g. Balboni et al, 2025; Grover and Kahn 2024)
  - **Contribution:** Default risk affecting aggregate adaptation
  - **Contribution:** Direct measure of aggregate adaptation
- Disaster Risk
  - Matters for asset prices and dynamics (e.g. Barro 2009, Gourio 2012)
  - **Contribution:** Additional feedback: protective capital

# Outline

## 1. Simple Model

- Analytical Results: spreads, climate change, and adaptation

## 2. Data

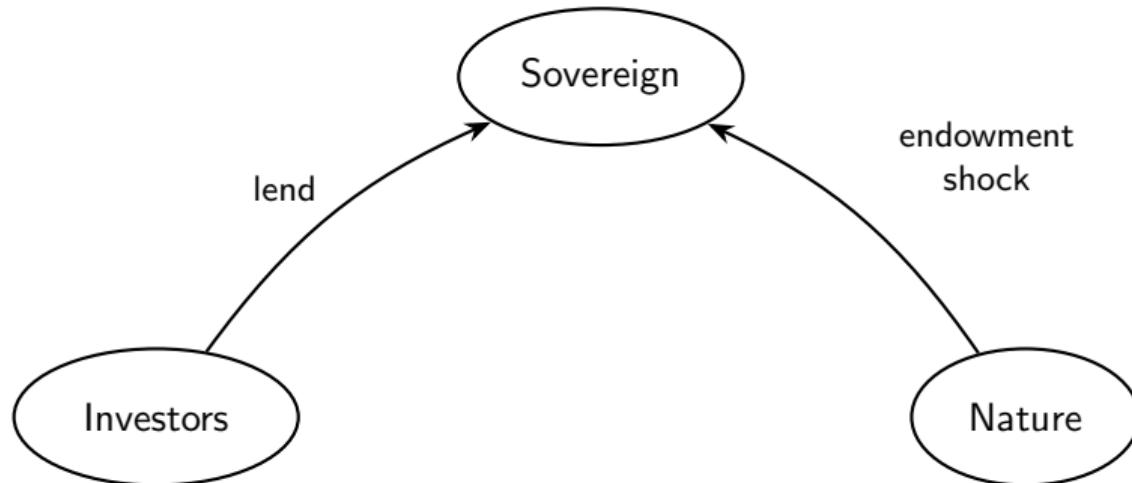

- A new measure of adaptation
- Validating the model

## 3. Quantitative Model

- Calibration using adaptation measure
- Quantitative Results: the adaptation trap
- Debt Relief Counterfactuals

# A Model of Sovereign Default

Objective:  $\max U$   
Choices: borrowing, default

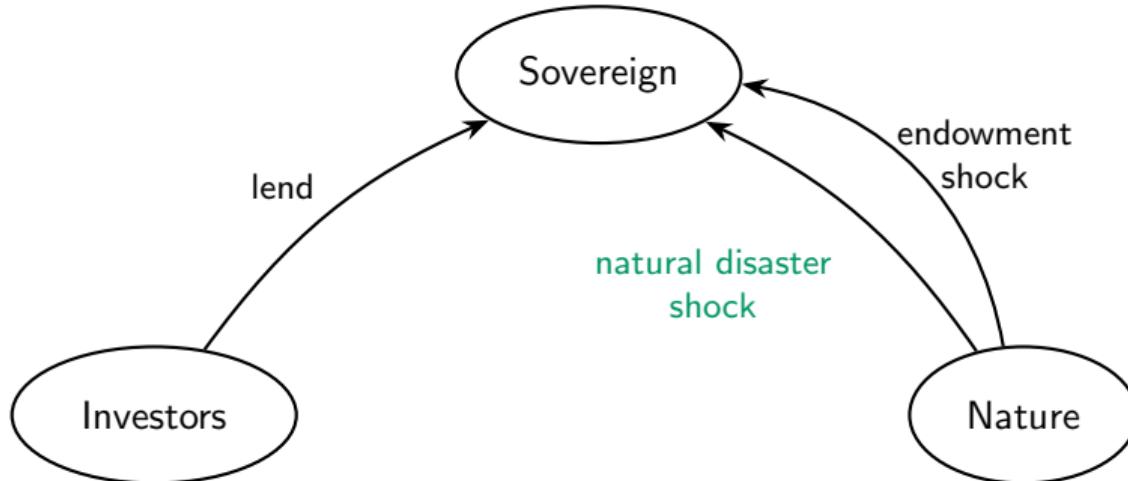

$$q = \frac{1-s}{1+r}$$

$$s = \Pr(\text{default}_{t+1})$$

# Sovereign Risk and Climate Risk

Objective:  $\max U$   
choices: default, borrowing, adaptation

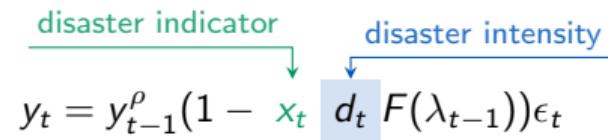

$$q = \frac{1-s}{1+r}$$

$$s = \Pr(\text{default}_{t+1})$$

# Model

$$y_t = y_{t-1}^\rho (1 - \textcolor{teal}{x}_t) d_t F(\lambda_{t-1}) \epsilon_t$$

disaster indicator      disaster intensity

$$\mathbb{P}(x_t = 1) = p$$

where  $d_t \stackrel{iid}{\sim} F_d(d)$ ,  $\log(\epsilon_t) \stackrel{iid}{\sim} N(\mu_\epsilon, \sigma_\epsilon^2)$

# Model

$$y_t = y_{t-1}^\rho (1 - \textcolor{teal}{x}_t) d_t F(\lambda_{t-1}) \epsilon_t$$

disaster indicator      disaster intensity

The diagram shows two input variables, "disaster indicator" and "disaster intensity", represented by green arrows pointing down to the term  $(1 - \textcolor{teal}{x}_t) d_t$  in the equation. The variable  $\textcolor{teal}{x}_t$  is highlighted in green.

$$\mathbb{P}(x_t = 1) = p$$

where  $d_t \stackrel{iid}{\sim} F_d(d)$ ,  $\log(\epsilon_t) \stackrel{iid}{\sim} N(\mu_\epsilon, \sigma_\epsilon^2)$

Sovereign maximizes utility:

$$U = \ln(C_1) + \beta \mathbb{E} \ln(C_2)$$

$$C_1 = y_1 + qB - \lambda_1$$

adaptation investment

The diagram shows the term  $qB$  as a component of consumption  $C_1$ , indicated by a blue arrow pointing from  $qB$  to the term  $qB$  in the equation. The variable  $\lambda_1$  is highlighted in blue.

$$C_2 = \begin{cases} y_2 - B & \text{if } D_2 = 0 \\ y_2 - \phi(y_2) & \text{if } D_2 = 1 \end{cases}$$

## Model: Default

Sovereign chooses to default if:  $B > \phi(y_2)$ .

Assume simple procyclical default costs:

$$\phi(y_2) = y_2 \bar{I} e^{\psi g}$$

## Model: Default

Sovereign chooses to default if:  $B > \phi(y_2)$ .

Assume simple procyclical default costs:

$$\phi(y_2) = y_2 \bar{I} e^{\psi g}$$

Therefore, default if the disaster adjusted growth rate is below an endogenous default threshold:

$$\underbrace{g + \frac{1}{1+\psi} \ln(1 - x_2 d_2 F(\lambda_1))}_{\tilde{g}} < \underbrace{\frac{1}{1+\psi} \ln \left( \frac{B}{\bar{I} y_1^\rho} \right)}_{\bar{g}(B)}$$

# Spread

Continuum of risk neutral investors implies:

$$q = \frac{1-s}{1+r} \quad s = \mathbb{P}(D_2 = 1) = \mathbb{P}(\tilde{g} < \bar{g}(B))$$

Analytical characterization:

$$s(B, \lambda) = (1-p)\Phi_g(\bar{g}) + pE_{d'} \left[ \Phi_g \left( \bar{g} - \frac{1}{1+\psi} \ln(1 - d_2 F(\lambda_1)) \right) \right]$$

# Climate Change, Adaptation, and the Spread

Proposition 1: The Spread is Increasing in Climate Change

$$\frac{\partial s}{\partial p} > 0$$

$$\hat{\Phi}_d \stackrel{\text{fosd}}{\geq} \bar{\Phi}_d \Rightarrow s(\cdot, \cdot | \hat{\Phi}_d) \geq s(\cdot, \cdot | \bar{\Phi}_d)$$

# Climate Change, Adaptation, and the Spread

Proposition 1: The Spread is Increasing in Climate Change

$$\frac{\partial s}{\partial p} > 0$$

$$\hat{\Phi}_d \stackrel{\text{fosd}}{\geq} \bar{\Phi}_d \Rightarrow s(\cdot, \cdot | \hat{\Phi}_d) \geq s(\cdot, \cdot | \bar{\Phi}_d)$$

Proposition 2: Spread decreasing in adaptation

$$\frac{\partial s}{\partial \lambda} < 0$$

$$\frac{\partial s}{\partial p} < \left. \frac{\partial s}{\partial p} \right|_{\lambda=0}$$

▶ proof

# Adaptation with Sovereign Risk

Adaptation trade-off:

- Counterfactual: no default option  $\rightarrow MC = MB$  damage reduction
- Now, additional effect through the spread

# Adaptation with Sovereign Risk

Adaptation trade-off:

- Counterfactual: no default option  $\rightarrow MC = MB$  damage reduction
- Now, additional effect through the spread

FOC( $\lambda$ ):

$$\underbrace{\frac{1}{C_1}}_{MC} = \underbrace{\beta \mathbb{E} \left( \frac{y'_2(\lambda)}{C_R} - s(\lambda) \frac{y'_2(\lambda)B}{y_2 C_R} \right)}_{MB \text{ damage reduction}} + \underbrace{\beta \mathbb{E} (s'(\lambda)(u(c_D) - u(c_R)))}_{MB \text{ reduced default prob}} - \underbrace{\frac{\frac{1}{1+r}s'(\lambda)B}{C_1}}_{MB \text{ lower spread}}$$

# Adaptation with Sovereign Risk

Adaptation trade-off:

- Counterfactual: no default option  $\rightarrow MC = MB$  damage reduction
- Now, additional effect through the spread

FOC( $\lambda$ ):

$$\underbrace{\frac{1}{C_1}}_{MC} = \underbrace{\beta \mathbb{E} \left( \frac{y'_2(\lambda)}{C_R} - s(\lambda) \frac{y'_2(\lambda)B}{y_2 C_R} \right)}_{MB \text{ damage reduction}} + \underbrace{\beta \mathbb{E} (s'(\lambda)(u(c_D) - u(c_R)))}_{MB \text{ reduced default prob}} - \underbrace{\frac{\frac{1}{1+r}s'(\lambda)B}{C_1}}_{MB \text{ lower spread}}$$

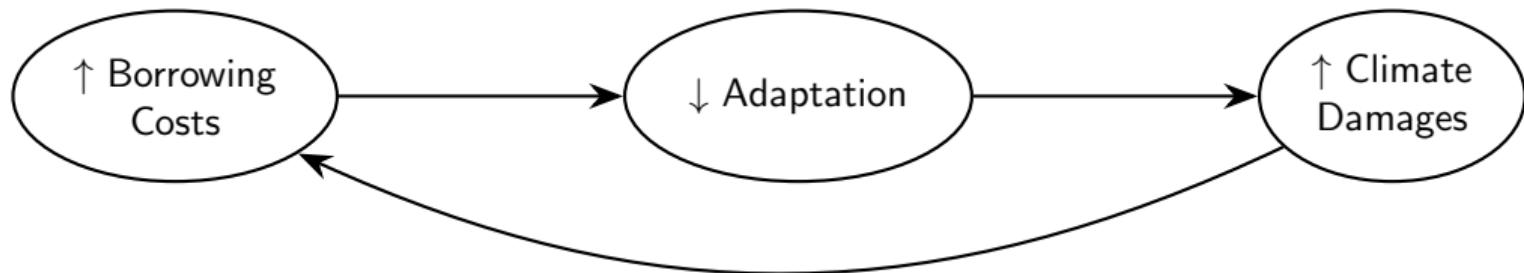

$\lambda^* \gtrless \lambda_c^*$  depends on the relative strength of these channels

For emerging markets:  $\lambda^* < \lambda_c^*$

► numerical

► intensive

## Adaptation Trap

# Roadmap

## 1. Simple Model

- Analytical Results: spreads, climate change, and adaptation

## 2. Data

- A new measure of adaptation
- Validating the model

## 3. Quantitative Model

- Calibration using adaptation measure
- Quantitative Results: the adaptation trap
- Debt Relief Counterfactuals

## Measuring Adaptation

No data on aggregate adaptation across countries

Macro literature: **latent variable approach**. Infer adaptation if (conditional on disaster size):

- High hazard exposure → lower damages
- Or, damages falling over time

# Measuring Adaptation

No data on aggregate adaptation across countries

Macro literature: **latent variable approach**. Infer adaptation if (conditional on disaster size):

- High hazard exposure → lower damages
- Or, damages falling over time

Adaptation is inferred, not observed

- Don't know what actions are taking place
- Panel variation and low power → can't compare across countries

Here: **direct measure** utilising data from government budgets

- Rich source of information on **spending by purpose**
- Generate a **dollar amount** spent

4. Cyclones increase sovereign risk, attenuated by adaptation

How quantitatively important is this sovereign risk - adaptation channel?

- What does it mean for the welfare effects of disasters? and climate change?
- Could debt relief help?

Infinite horizon extension of model

- Long term debt, adaptation capital

## Quantitative Model

Law of motion for adaptation:

$$\Lambda_t = (1 - \delta)\Lambda_{t-1} + \lambda_{t-1}$$

## Quantitative Model

Law of motion for adaptation:

$$\Lambda_t = (1 - \delta)\Lambda_{t-1} + \lambda_{t-1}$$

Bond issued at  $t$  promises an infinite stream of coupons, which decreases at a constant rate  $\psi$

Resource constraint:

$$C_t = \begin{cases} y_t + q_t(b_{t+1} - (1 - \psi)b_t) - b_t - \lambda_t & \text{if } D_t = 0 \\ y_t - \phi(y_t) - \lambda_t & \text{if } D_t = 1 \end{cases}$$

Regain access w.p.  $\eta$ .

## Quantitative Model

Law of motion for adaptation:

$$\Lambda_t = (1 - \delta)\Lambda_{t-1} + \lambda_{t-1}$$

Bond issued at  $t$  promises an infinite stream of coupons, which decreases at a constant rate  $\psi$

Resource constraint:

$$C_t = \begin{cases} y_t + q_t(b_{t+1} - (1 - \psi)b_t) - b_t - \lambda_t & \text{if } D_t = 0 \\ y_t - \phi(y_t) - \lambda_t & \text{if } D_t = 1 \end{cases}$$

Regain access w.p.  $\eta$ .

Bond price:

$$q_t = \frac{1}{1+r} \mathbb{E} ((1 - D_{t+1}) + (1 - \psi)(1 - D_{t+1}q_{t+1}))$$

## Functional Forms

Quadratic costs of default:

$$\phi(y) = \max \{-d_0 y + d_1 y^2, 0\}$$

CRRA utility:

$$U(c) = \frac{c^{1-\gamma}}{1-\gamma}$$

Adaptation benefits:

$$F(\Lambda_t) = \exp \left( -\alpha \Lambda_t^{1/\alpha} \right)$$

## Functional Forms

Quadratic costs of default:

$$\phi(y) = \max \{-d_0y + d_1y^2, 0\}$$

CRRA utility:

$$U(c) = \frac{c^{1-\gamma}}{1-\gamma}$$

Adaptation benefits:

$$F(\Lambda_t) = \exp \left( -\alpha \Lambda_t^{1/\alpha} \right)$$

Solution issues with sovereign default models + additional endogenous state

- Augment with extreme value taste shocks ► solution

## Calibration Strategy: Population Weighted Caribbean

1. Standard parameters:  $\eta$ ,  $\gamma$ ,  $\delta$

## Calibration Strategy: Population Weighted Caribbean

1. Standard parameters:  $\eta, \gamma, \delta$
2. Calibrated externally from data:  $r, \psi, p, \rho, \mu_\epsilon, \sigma_\epsilon, \sigma_d$

- Estimate:

$$\log(y_t) = \rho \log(y_{t-1}) - \xi x_t + \varepsilon_t$$

- Model counterpart:

$$\xi_t = F(\Lambda_t)d_t$$

# Calibration Strategy: Population Weighted Caribbean

1. Standard parameters:  $\eta, \gamma, \delta$
2. Calibrated externally from data:  $r, \psi, p, \rho, \mu_\epsilon, \sigma_\epsilon, \sigma_d$

- Estimate:

$$\log(y_t) = \rho \log(y_{t-1}) - \xi x_t + \varepsilon_t$$

- Model counterpart:

$$\xi_t = F(\Lambda_t)d_t$$

3. Jointly calibrated to target moments:

- $\mu_d$ : mean GDP loss from disaster,  $\xi$
- $\alpha$ : adaptation investment to GDP ratio
- $\beta$ : debt to GDP ratio
- $d_0$ : mean spread
- $d_1$ : std dev spread

▶ calibration

# Model Performance

<i>Welfare Loss</i>		
	5.1%	

---

# Sovereign Risk Restricts Adaptation

Simulated Moments: Caribbean		
Moment	Model	No Default Counterfactual
Adaptation Investment/GDP	0.003	+13%
GDP loss per Hurricane	0.05	-10%
Welfare loss from Hurricanes	5.1%	4.62%

- GDP loss from a hurricane is 10% larger due to the sovereign risk- adaptation channel
- This gap increases to 13% with a projected increase in frequency and severity by end of century
  - 29.1% increase in  $p$ , 48.5% increase in  $\mu_d$

## Sovereign Risk Restricts Adaptation

Split sample: high and low sovereign risk

- Re-calibrate debt parameters:  $\beta, d_0, d_1$
- Keep climate and adaptation parameters

# Sovereign Risk Restricts Adaptation

Split sample: high and low sovereign risk

- Re-calibrate debt parameters:  $\beta, d_0, d_1$
- Keep climate and adaptation parameters

	Low Risk		High Risk	
	Model	Data	Model	Data
Adaptation Investment/GDP	0.38%	0.39%	0.29%	0.27%
Debt/GDP	0.49	0.51	0.37	0.38
Mean Spread	460	442	573	559

Model accounts for differences in adaptation expenditure across economies with differing sovereign risk.

## Policy Counterfactual: Interest Free Loan

IMF Resilience and Sustainability Trust:

- New lending facility established 2022
- Long term funding for climate preparedness

## Policy Counterfactual: Interest Free Loan

IMF Resilience and Sustainability Trust:

- New lending facility established 2022
- Long term funding for climate preparedness

Consider loan 10% of pre-loan output, 3 year grace period

- Default free due to seniority → at risk free rate

$$\tilde{F} = r(1+r)^g F$$

## Policy Counterfactual: Interest Free Loan

Simulated Moments: Caribbean			
Moment	Baseline	No Default	Loan Counterfactual
Adaptation Investment/GDP	0.003	+13%	+5%
GDP loss per Hurricane	0.05	-10%	-4%
Welfare loss from Hurricanes	5.1%	4.62%	4.87%

## Policy Counterfactual: Adaptation Bond

Increase in prevalence of 'green bonds'

- Mostly corporate, and 'use of proceeds'
- Now some mitigation outcome-linked bonds e.g. Chile

## Policy Counterfactual: Adaptation Bond

Increase in prevalence of 'green bonds'

- Mostly corporate, and 'use of proceeds'
- Now some mitigation outcome-linked bonds e.g. Chile

Here consider an 'Adaptation Bond'

- $c\%$  coupon reduction if adaptation capital 5% larger

$$q_t^{AB} = \frac{1}{1+r} \mathbb{E} \left( (1 - D_{t+1})(1 - c \mathbb{1}_{A_{t+1} > A^*}) + (1 - D_{t+1})(1 - \psi) q_{t+1}^{AB} \right).$$

## Policy Counterfactual: Adaptation Bond

Two countervailing effects on  $s$ :

1.  $\downarrow$  Default risk  $\rightarrow s \downarrow$
2. State contingency  $\rightarrow$  lenders require a premium

Spread minimizing  $c = 2.2\%$

## Policy Counterfactual: Adaptation Bond

Two countervailing effects on  $s$ :

1.  $\downarrow$  Default risk  $\rightarrow s \downarrow$
2. State contingency  $\rightarrow$  lenders require a premium

Spread minimizing  $c = 2.2\%$

Simulated Moments: Caribbean				
Moment	Baseline	No Default	Bond	Counterfactual
Adaptation Investment/GDP	0.003	+13%		+10%
GDP loss per Hurricane	0.05	-10%		-8%
Welfare loss from Hurricanes	5.1%	4.62%		4.70%

# Conclusion

Sovereign Risk restricts adaptation and increases the costs of disasters

- **Theory:** Framework integrating sovereign risk, climate risk, and adaptation
  - Adaptation Trap
- **Data:** New dataset of adaptation expenditures
  - Robust negative correlation between sovereign risk and adaptation
  - Adaptation attenuates sovereign risk effects of disasters
- **Quantitative:** Quantitative model matches Caribbean data
  - Hurricanes have a 10% larger effect through restricted adaptation
  - This wedge grows with climate change
  - Debt relief can help: adaptation bond, interest free loan

## Proofs: Proposition 1

$$\frac{\partial s}{\partial p} = -\Phi_g(\bar{g}) + \int \Phi_g\left(\bar{g} - \frac{1}{1+\psi} \ln(1 - d(F(\lambda)))\right) d\Phi_d(d')$$

- Support of  $\Phi_d$  is  $[0, 1]$ .
- Therefore  $\frac{\partial s}{\partial p} > -\Phi_g(\bar{g}) + \int \Phi_g(\bar{g}) d\Phi_d(d') = 0$

Suppose  $\hat{\Phi}_d$  first-order stochastic dominates  $\Phi_d$ .

- Let  $\hat{s}$  denote the spread function associated with the damage distribution  $\hat{\Phi}_d$ .
- Since  $\Phi_g\left(\bar{g} - \frac{1}{1+\psi} \ln(1 - d(F(\lambda)))\right)$  is increasing in  $d'$ , it follows that

$$E\left[\Phi_g\left(\bar{g} - \frac{1}{1+\psi} \ln(1 - d(F(\lambda)))\right) \middle| \hat{\Phi}_d\right] \geq E\left[\Phi_g\left(\bar{g} - \frac{1}{1+\psi} \ln(1 - d(F(\lambda)))\right) \middle| \Phi_d\right].$$

▶ back

## Proof: Proposition 2

$$\frac{\partial s}{\partial \lambda} = p E_{d'} \left[ \phi_g \left( \bar{g} - \frac{1}{1+\psi} \ln(1 - d(F(\lambda))) \right) \cdot \frac{d \cdot F'(\lambda)}{(1+\psi)(1-d \cdot F(\lambda))} \right] < 0$$

- first term inside the square brackets is positive
- Second is negative given the assumption on the domain of  $d$  and  $F(\lambda)$  is decreasing in  $\lambda$

▶ back

## Adaptation Trap

	$p = 0.1, \alpha = 2$	$p = 0.1, \alpha = 1.1$	$p = 0.5, \alpha = 2$	$p = 0.5, \alpha = 1.1$
$\bar{I}$ min	NA	0.91	NA	0.87
implied $s$ (bps)	NA	21	NA	28

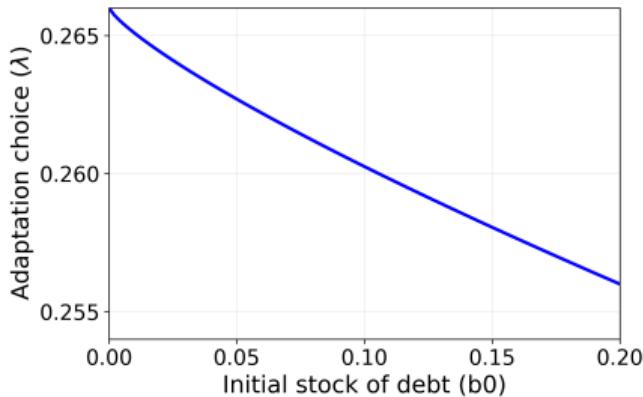

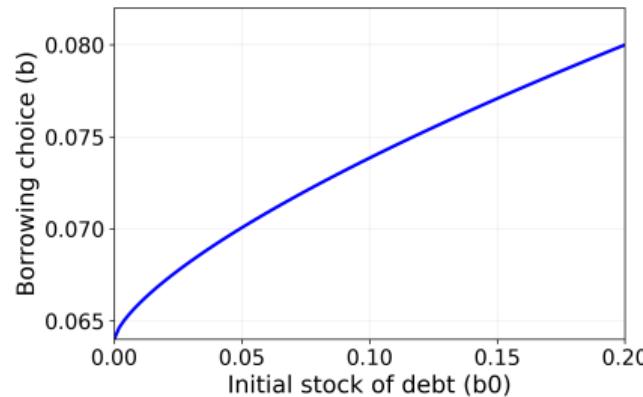

**Table:** The table shows the minimum value for default costs that imply that adaptation is higher under default risk than without for a set of combinations of the probability of a disaster and adaptation effectiveness.

$$F(\lambda) = \exp\left(-\alpha\lambda^{1/\alpha}\right).$$

# Word Embeddings

Word embedding: real-valued vector representation of a word

- Words closer in the vector space are expected to be similar in meaning
- Use GloVe model from Stanford NLP group trained on my adaptation corpus

# Word Embeddings

Map co-occurrences of words into a meaningful space

Context of a term  $w_{d,n}$  in a vocabulary  $V$ :

$$C(w_{d,n}) = (w_{d,n-L}, \dots, w_{d,n-1}, w_{d,n+1}, w_{d,n+L}).$$

Co-occurrences are defined by a  $V \times V$  matrix

- Entry  $W_{i,j}$  is the number of times that term  $i$  appears within the context of  $j$ , and vice versa.
- Standard:  $L = 10$ ,  $K = 200$ .

Each term is associated with a vector  $\rho_v$  in  $\mathbb{R}^K$ , chosen to solve:

$$\min_{\rho_v} \sum_{i,j} f(W_{i,j}) (\rho_i^T \rho_j - \log(W_{i,j}))^2$$

$f(\cdot)$  is a non-negative, increasing, and concave weighting function.

## Sample

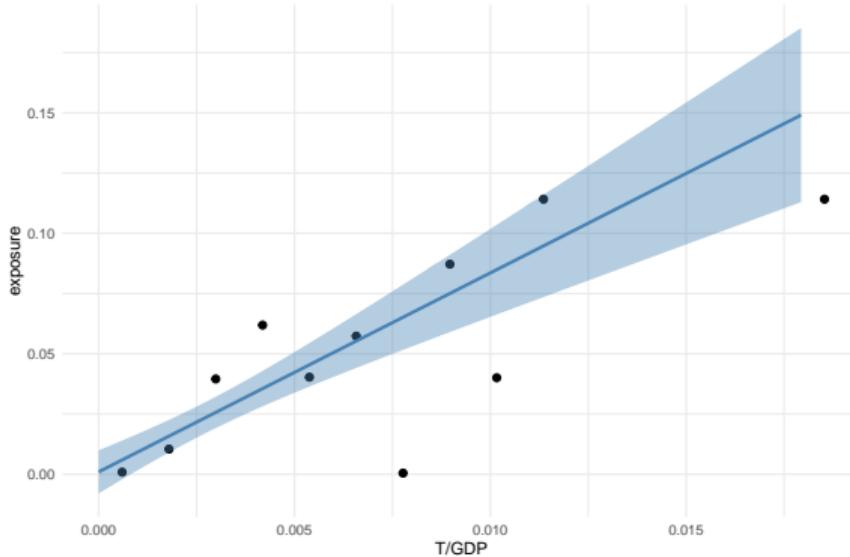

- Latin America: 18 sovereigns. Caribbean: 13 sovereigns
- Lose 2 due to language
  - Haiti, Brazil
- Lose 3 due to lack of rating
  - Saint Lucia, Antigua + Barbuda, Dominica
- Lose 7 due to lack of machine readability
  - Trinidad and Tobago, Cuba, Bolivia, El Salvador, Nicaragua, Paraguay, Venezuela
- Lose 74 country-year observations due to lack of availability

Final sample: Unbalanced panel of 19 economies 2014-2025

- 163 country-year observations

# Data

## 1. sovrate:

- Index from 0-21
- From World Bank

## 2. exposure:

- wind speed (maximum yearly), scaled by land area
- From GeoMet database (Felbermayr and Gröschl)

## 3. government effectiveness:

- World Bank Index
- captures “perceptions of the quality of public services, the quality of the civil service and the degree of its independence from political pressures, the quality of policy formulation and implementation, and the credibility of the government’s commitment to such policies.”
- Sources include: institutional effectiveness from the Economist Intelligence Unit, likelihood of infrastructure disruption, state failure or political instability from S&P Global, and quality of financial and revenue management.

## Model

$$y_t = y_{t-1}^\rho (1 - \textcolor{teal}{x_t} \ d_t (1 - \Lambda_t)) \epsilon_t$$

Law of motion for adaptation:

$$\Lambda_t = (1 - \delta) \Lambda_{t-1} + \lambda_{t-1},$$

## Model

$$y_t = y_{t-1}^\rho (1 - \textcolor{teal}{x_t} \textcolor{blue}{d_t} (1 - \Lambda_t)) \epsilon_t$$

Law of motion for adaptation:

$$\Lambda_t = (1 - \delta) \Lambda_{t-1} + \lambda_{t-1},$$

Bond issued at  $t$  promises an infinite stream of coupons, which decreases at a constant rate  $\psi$ .

Resource constraint:

$$C_t = \begin{cases} y_t + q_t(b_{t+1} - (1 - \psi)b_t) - b_t - f(\lambda_t) & \text{if } D_t = 0 \\ \phi(y_t)y_t - f(\lambda_t) & \text{if } D_t = 1, \end{cases}$$

where  $\phi(y_t)$  is the endowment cost of default. Regain access w.p.  $\eta$ . Bond price:

$$q_t = \frac{1}{1+r} \mathbb{E} ((1 - D_{t+1}) + (1 - \psi)(1 - D_{t+1}q_{t+1})).$$

► recursive equilibrium

► back

## Recursive Equilibrium

Restrict attention to Markov Perfect Equilibria.

Equilibrium defined by:

- 1) a set of value functions for the representative household: total value  $V$ , the value with market access  $V_{nd}$ , and the value in default  $V_d$ :

$$V = \max_D \{(1 - D)V_{nd} + DV_d\}, \quad (1)$$

$$V_{nd}(y, b, \Lambda) = \max_{b', \Lambda'} u(c) + \beta \mathbb{E}[V(y', b', \Lambda')], \quad (2)$$

$$V_d(y, 0, \Lambda) = \max_{\Lambda'} u(c) + \beta \mathbb{E}[(1 - \eta)V_d(y', 0, \Lambda') + \eta V(y', b', \Lambda')], \quad (3)$$

- 2) government policies for default  $D$ , bond issuance  $b$ , and adaptation  $\Lambda$ , and
- 3) a government debt price function  $q$  such that:

- the debt price function is consistent with optimization by foreign lenders,
- the value functions and the policy functions solve the maximization problem,
- and the resource constraint of the household is satisfied.

# Solution Algorithm

Discretize output, debt, adaptation.

Iterative algorithm:

1. Initial guesses for the unconditional debt price function and for the value functions
2. Update the value function  $V_{nd}$  by solving the maximization problem in the market access case
  - Each possible choice associated with an additive taste shock.
  - Sovereign chooses  $b'$  conditional on a particular  $\Lambda'$ , and that  $\Lambda'$  is chosen for a fixed  $b'$ .
  - Probability of choosing a given discrete value is given by the multinomial logit formula.
3. Update the value function  $V$  by solving the discrete choice default problem.
  - Introduce extreme value shocks to the default problem.
4. Update the default value function  $V_d$  making use of the update values of  $V$  and  $V_{nd}$ .
5. Repeat (2-4) until value functions have converged.
6. Update the unconditional debt price function by imposing the default policy and the average equilibrium price function.
7. Repeat (2-6) until convergence of the unconditional debt price function.
